ABSTRACT

Saadani-Wami-Mbiki wildlife corridor has been facing conservation threats as a result of various land-use practices (LUP) carried out in and around the corridor. The understanding of changes happening in the corridor over time is important for establishing the management baseline data. This study aimed at identifying land use practices along the Saadani-Wami-Mbiki wildlife corridor and their implications to wildlife conservation. Specifically, the study sought to determine the rate of land cover changes in the corridor between 1975 and 2011 and the effects associated with land use practices on wildlife conservation. The land sat imageries of 1975, 1995, and 2011 were used to assess the rate of vegetation cover changes as a result of various land use practices carried out along. The household survey and Key informants’ interview methods were used to obtain socio-economic data which were analyzed using SPSS while GIS data were analyzed using the ERDAS IMAGINE 9.1 and ArcGIS 9.3 programs. In the past 36 years (1975-2011), the cultivated land increased by 25%, settlement by 13%, open forest by 10% while closed forest and grassland decreased by 18% and 3% respectively. Shifting cultivation, overgrazing, charcoal burning, settlements, and poaching were identified as major land use practices threatening wildlife conservation within the corridor. Based on the results, it was recommended that, the Government...
should formulate a land use management plan and introduce a community-based natural resources management strategy to improve natural resources utilization and reduction of human stress to the corridor.

Keywords: Wami-Mbiki; Saadan National Park; Wildlife Corridor; pastoralist; Wami River land use practices.

1. INTRODUCTION

The rapid loss of biodiversity and habitat around the world is occurring as a result of farmers clearing land for new fields, settlements, and logging [1]. In Tanzania, shifting in land use patterns has caused rapid degradation that has led to the reduction of biodiversity in various protected areas resulting in natural habitat destruction [2-4]. Following these practices, some protected areas are now becoming ecological islands because of emerging various land use practices. These results in blockage of animals’ routes i.e. Wildlife corridors, dispersal areas, foraging grounds, salt licking areas and breeding sites leading to loss of wildlife critical areas [5-6]. Wildlife corridors are central to the health of the wildlife, but have been interfered with and shrinking as a result of various land use practices that are carried out in and around them (Vincent et al., 1999). In Tanzania, corridors have been easily invaded because of a lack of legal protection status. The study was done by Noe [7] between Mt. Kilimanjaro and Amboseli National Parks revealed that settlement and agriculture have resulted in reducing the actual size of the corridor from approximately 21 km² in 1952 to 5 km² in 2001. This also has caused changes in the number of migratory routes and wildlife distribution. Some corridors, such as Kwakuchinja and Kitendeni are seriously threatening the ecological integrity because they are under very intensive pressure of agriculture, settlement and extensive livestock grazing [8-9].

Wildlife corridors secure the integrity of physical environmental processes that are essential for the requirements of particular species [10]. For a population to be in good health and be able to reproduce needs some factors such as sufficient foraging area and its habitat which most of the protected areas do not meet. This marks the necessity to have the corridors linking Protected Areas allowing animals dispersal in searching for their basic needs, maintain and sustain viable populations [11]. Moreover, corridors are the key to the survival of wildlife and ecosystems. They are important for the conservation of wildlife by acting as an extension of the core protected areas and hence contribute to maintaining the biodiversity inside and outside the core protected areas.

This is done by maintaining the genetic variation in populations where inbreeding is inevitable [12]. This enhances colonisation, recolonization, and prevention of inbreeding through gene flow which increases genetic variation. As a result, the vigour for the animal is increased enabling it to cope with its environment. In addition, they provide refugia when the environment in the territorial areas becomes adverse, increases foraging areas, and lowers diseases incidences. Therefore, protection, restoration, and establishment of wildlife corridors are referred to as the appropriate measures to improve the ecological values of ecosystems by manifesting ecological networking [6,13] Jimenez-Osorio et al., 2008). The focus of this study was to identify various land use practices carried out along the Saadani-Wami-Mbiki Wildlife Management Area and their implications for wildlife conservation.

2. MATERIALS AND METHODS

Study Site Description.-The Saadani-Wami-Mbiki Wildlife Corridor lies in the coastal area of Tanzania (Fig. 1). The corridor links Saadani National Park and Wami-Mbiki Wildlife Management Area. The corridor lies on the northern side and is about 80 km from the major commercial city of Dar es Salaam. The area occupied by the corridor is interspersed with rocky hills of thin soil cover and valleys with deep clay or alluvial soils; altitude varies between 350 and 400m. The corridor can easily be accessed by road in some areas e.g. from Chalinze - Segera road through Mandela village. The size of the corridor is estimated to be about 62 km long and 10 km wide.

Sampling Procedure: A cross-sectional design which allows data to be collected at one point in time was adopted as suggested by Kothari, [14] and Saunders et al., [15]. Based on the list of villages from the District Office and
A reconnaissance survey, a purposive sampling method was used to select three villages namely Matipwili, Mandela and Pongwe Msungura. The villages were selected based on location concerning accessibility and proximity to the corridor. The sampling units of 30 households in each village were randomly selected from the sampling frame (village register). This sample size is recommended by Saunders et al., [15] on grounds that it is a reasonable sample size for socio-science studies as it is statistically large enough to make scientific conclusions. In most African traditions and customs, the household is the basic unit of social structure.

The survey was conducted using a structured questionnaire containing both open and closed-ended questions (Appendix I). The method was used to obtain information on land use practices, socio-economic and cultural activities undertaken in and along the corridor. Also, the technique was used to obtain villagers' views on the remarkable impacts associated with these land use practices on the corridor and wildlife. Key informants included individuals who were conversant with their environment and willing to talk to the researcher. They also included the most influential people in the village such as District Game Officer (DGO), Village Game Scouts (VGS), Village Agricultural Extension Officers, and Wami-Mbiki WMA and Saadani National Park Officials. The discussion was guided by a checklist (Appendix II) and aimed at collecting information concerning the types of land use practices done in and around the corridor and their associated impact on wildlife conservation. Furthermore, the collected information was on the trend of wild animals and human-wildlife interaction within and along the corridor. This was supplemented by direct observation and secondary data which included various documents and publications obtained through grey literature, literature search using the Internet and from Wami-Mbiki WMA office.

![Fig. 1. Location of the corridor and study villages](image-url)
2.1 Data Analysis

Quantitative data from household surveys were processed and analyzed using Statistical Package for Social Sciences (SPSS) version 12.0 computer program and Microsoft Excel Spreadsheet. Descriptive statistics were applied to determine frequencies, percentages, and multiple responses. The qualitative data were analyzed using content and structural-functional analysis techniques. The content analysis method was used to analyze in detail the components of verbal discussions held with key informants and from open-ended questions.

Remote sensing and GIS techniques were employed to assess vegetation cover changes as a result of land use systems along the corridor. Three sets of Landsat satellite imageries for 1975, 1995, and 2011 were purchased by considering the possible minimum presence of cloud cover, Spatio-temporal characteristics, image data availability, and image data costs. Image pre-processing, rectification/geo-referencing, enhancement, and correction for distortions for all acquired images were done. The researcher used a handheld GPS for ground-truthing/geo-referencing purposes. This was used to coordinate which later on were applied in allocating features for verifying and documenting types and magnitude of vegetation cover change in the area.

2.2 Materials

The study used Multispectral Scanner (MSS) of 27th July 1975, Landsat 7 ETM+ imagery of 27th July 1995, and Landsat 7 ETM+ of 21st February 2011. The images were obtained from the Institute of Resources Assessment (IRA) of the University of Dar es Salaam. Topographical maps with a scale of 1:50,000 were acquired from the Survey and Mapping Division of the Ministry of Lands, Housing and Human Settlements Development for geo-referencing Landsat images preparation of land use/cover interpretation key. The sub-scenes covering the Saadani-Wami-Mbiki wildlife corridor were extracted from the mentioned images. Global Positioning System (GPS) was used in land use and cover map verification and updating land use and land cover map to include land use pattern up to year 2011. Images were selected based on low cloud cover, seasonality, date and phonological effects. Supervised Maximum Likelihood Classifier (MLC) remote sensing classification methodologies were utilized to create a base map for ground-truthing. Supervised classification process involved classification of training sites on the image which represent specific land classes to be mapped.

2.3 Data Analysis

Assessment of the rate of cover change. The estimation for the rate of change for the different covers was computed based on the following formulae; [16]

\[ \text{% Change}_{year} = \frac{\text{Area}_{year} - \text{Area}_{year+1}}{\sum_{i=1}^{n} \text{Area}_{year}} \times 100 \]  

(1)

Annual rate of change = \[ \frac{\text{Area}_{year} - \text{Area}_{year+1}}{t_{years}} \]  

(2)

Where; Area \( i_{year} \) = area of cover \( i \) at the first date

\[ \sum_{i=1}^{n} \text{Area}_{year} \] = the total cover area at the first date and

\( t_{years} \) = period in years between the first and second scene acquisition dates

3. RESULTS

The spatial extents of different land cover classes: The mainland use/land cover maps for 1975, 1995 and 2011 are presented in Figs 4, 5 and 6 respectively. Analysis shows that in the year 1975 (see Fig. 2) the land use/cover in the study area was dominated by closed forest and bushland occupying 30% (59 413 ha) and 25% (50 788 ha) respectively followed by cultivated land occupying 13% (26 165 ha) then grassland 13% (26 165 ha) then grassland comprising 1% (1 095 ha).

Others were open forest and settlement, occupying 4% (8 599 ha) and 4% (7 618 ha) respectively and finally, open water bodies comprising 1% (1 095 ha).

Fig. 3 shows that in 1995, closed forests continued to occupy the largest land cover. It comprised 23% (46 681 ha) of the total land cover, followed by cultivated land 18% (35 608 ha). Bushland and shrubland occupied 13% (26 616 ha) and 13% (25 362 ha) respectively.
Others included settlement and grassland which occupied 12% (24,474 ha) and 11% (22,812 ha) respectively. The open forest occupied 9% (18,493 ha) and open water bodies 1% (1,095 ha).

In 2011, the cultivated land occupied 38% (76,791 ha) followed by settlement which counted for 19% (37,282 ha) of the total area (Fig. 4). Furthermore, the closed forest occupied 17% (33,392 ha) followed by bushland 12% (24,509 ha), open forest 8% (15,577 ha), grassland 6% (12,690 ha), and open water bodies that occupied 0.01% (900 ha).

Areas used for cultivation and settlement seemed to be increasing gradually throughout the study period from 26,165 ha (13%) and 7,618 ha (4%) in 1975 to 76,791 ha (38%) and 37,282 ha (19%) in 2011 while closed forest, grassland, and bushland decreased from 59,413 ha (30%), 24,278 ha (12%) and 50,788 ha (25%) in 1975 to 33,392 (17%), 12,690 ha (6%) and 24,509 ha (12%) in 2011 respectively (Fig. 5). The combined land cover areas of closed forest, grassland, and bushland decreased from 134,479 ha (67%) in 1975 to 70,591 ha (35%) in 2011. The areas used for cultivation increased from 26,165 ha (13%) to 76,791 ha (38%) in the same period. Also, the area used for settlement increased tremendously from 7,618 ha (4%) in 1975 to 37,282 ha (19%) in 2011.

---

Fig. 2. Land cover/use Map of Image scene, 1975

Fig. 3. Land cover/use Map of Image scene, 1995
Changes in land use/cover in the Saadani-Wami-Mbiki wildlife corridor: According to Table 1, the period between 1975 and 1995 show that the cultivated area increased by 9443 ha (5%); bushland decreased by 24 172 ha (12%) while the area for grassland shrunk by 1466 ha (1%). In the same period, settlement increased significantly by 16 856 ha (8%) as opposed to a closed forest which indicated a decrease by 12 732 ha (6%) while open forests and shrubs recorded an increase by 9894 ha (5%) and 3355 ha (2%) respectively.
Moreover, in the period between 1995 and 2011, the closed forest decreased by 13,289 ha (7%), grassland by 10,122 ha (5%), shrubs by 25,362 ha (13%), and bushland by 2,107 ha (1%) while the open forest decreased by 2,916 ha (1%) (Table 1). However, the cultivated land increased by 41,183 ha (20%) and settlement by 12,808 ha (6%).

**Rate of land use/cover change in the Saadani-Wami-Mbiki Wildlife corridor:** Tables 2 and 3 show the rate of land use/cover change in the Saadani-Wami-Mbiki wildlife corridor. It was found that grassland decreased at a rate of 73 ha (0.1%) per year between 1975 and 1995 and continued decreasing at the rate of 633 ha (0.3%) per year between 1995 and 2011. Furthermore, it was revealed that the closed forest decreased at the rate of 637 ha/year (0.3%) between 1975 and 1995 while decreasing at the rate of 831 ha/year (0.4%) in the period between 1995 and 2011. In addition, it was found that cultivated land increased at a rate of 472 ha (0.3%) per year between 1975 and 1995 and at a rate of 2,574 ha (1.3%) per year between 1995 and 2011. Bushland decreased at the rate of 1,209 ha (0.6%) per year between 1975 and 1995 and 332 ha (0.1%) per year between 1995 and 2011. In addition, settlement increased at the rate of 843 ha (0.4%) per year between 1975 and 1995 and 801 ha (0.4%) per year between 1995 and 2011. The open forest increased at the rate of 495 ha (0.3%) per year between 1975 and 1995 and continued increasing at the rate of 182 ha (0.1%) per year between 1995 and 2011. The other land cover that seemed to be changing was shrubs which indicated that they increased at the rate of 168 ha (0.1%) per year between 1975 and 1995 and decreased at the rate of 1,585 ha (0.8%) per year between 1995 and 2011.

**Changes detection matrix of different land use/cover:** The change detection of land cover/use in the corridor between 1975 and 1995 is presented in Table 4. During this period, 5,202 ha of closed forest was converted to bushland, 3,980 ha to cultivated land, 759 ha to settlements, 7,412 ha to grassland, 10 ha to open forest, 10,226 ha to shrubland while 15,851 ha remained unchanged. The bushland experienced the same sequence whereby 3,530 ha were converted to grassland, 3,230 ha to cultivated land, and 874 ha to settlements while 5,331 ha remained unchanged. Furthermore, 1,268 ha of open forest were converted to bushland, 330 ha to cultivated land, 728 ha to grassland, 1,373 ha to shrubland, and 40 ha to settlement while 750 ha remained unchanged. About 6,167 ha of shrubland were converted to cultivated land, 1,733 ha to settlements, 3,337 ha to grassland while 1,792 ha remained unchanged.

The analysis of land use/cover change detection for the period between 1995 and 2011 is presented in Table 5. The closed forests changed by 1,716 ha to grasslands, 4,190 ha to cultivated land, 1,491 ha to settlements, 2,090 ha to bushland, 4 ha to open forest, 4,480 ha to shrubland while 1,457 ha remained unchanged.

About 8,047 ha of the open forest were converted to bushland, 4,058 ha to cultivated land, 3,483 ha to grassland, and 3,950 ha to settlements while 4,117 ha remained unchanged. About 4,865 ha of bushland were converted to grassland, 5,155 ha to cultivated land while 393 ha remained unchanged. Also, 1,959 ha of grassland were converted to cropland, 1,240 ha to settlements while 1,347 ha remained unchanged.

**Land use practices (LUP) along Saadani – Wami-Mbiki Wildlife corridor:** Results in Table 6 show various land use practices that were identified along Saadani – Wami-Mbiki wildlife corridor. It was revealed that 23% of the local community was involved in shifting cultivation. Furthermore, it was found that 21% of the local community was involved in livestock keeping. In addition, charcoal burning activity was performed by 17% of all local communities in the area. Other activities included poles extraction and fishing.

The perception of the local community on the implications of various land use practices to Wildlife Conservation: About 24% of the respondents perceived loss of habitat as the implication of various LUPs along the corridor (Table 7). Furthermore, 17% of the local community indicated that the various LUPs in the area caused disturbance of the wildlife movement. Other implications of LUP activities in the area were land degradation, reduction of animal fodders, declined animal populations, and blockage of the corridor.

**4. DISCUSSION**

**Rate of land use/cover change in the corridor:** Results presented in Fig. 4, 5, and 6 revealed that there were different rates of land use/vegetation cover changes as observed in the analyzed satellite imageries of 1975, 1995, and

2011. This could be attributed to an increase in the human population in the area as the population increased from 173,871 to 228,967 during the period 1988–2002 with an average annual growth rate of 2% [17]. The major population pulling factors to this area included adequate and fertile land to cater for livelihoods through cultivation, settlements, livestock keeping, and charcoal making, amongst others. The introduction of new crops for commercial purposes such as sesame and pineapples in the area has also attracted people to open new virgin lands which are more fertile to maximize production. Loss of corridors for agriculture and other land uses is common in many parts of Tanzania. Jones et al., [18] for example, reported that the Mikumi–Wami-Mbiki and Tarangire – Lake Manyara Corridors were under increasing pressure due to cultivation, human settlements, charcoal making, and extraction of timber/poles. Furthermore, the study by Noe [7] found that the increase in population along the Kitendeni Wildlife Corridor created more demand on land for cultivation and settlement.

**Furthermore:** Results showed that shifting cultivation was among the land use practices being undertaken in the area. This could have been caused by factors such as population growth, lack of land use management plan, loss of soil fertility, inefficient agricultural extension services, and poverty of local communities in the area. The study was done by Rahman et al., [19] in Eastern Bangladesh, reported that population pressure influence farmers' decision to continue shifting cultivation. Furthermore, URT [17] reported that population increase lead to opening more land for production while increasing pressure over resources. In the same vein, Ntongani et al. [4] reported that an increase in population in Selous-Niassa Corridor resulted in shifting cultivation ending up degrading the corridor.

In addition, the poverty of local communities along the corridor has been the driving factor for shifting cultivations. This is because local communities are primarily subsistence farmers and fail to go for alternatives such as the purchase of fertilizers. Thus, the only option for the local community in this area was to open new virgin land for cultivation. The study was done by Rahman et al. [19] in Eastern Bangladesh found that villagers who are primarily subsistence farmers produce enough foods for their family’s survival as their priority on agricultural production. In some regions, poverty-driven cultivation can occur if small-scale and subsistence farmers lack resources or secure land tenure and are forced to move into forested areas to grow food and earn their livelihoods [20]. Particularly in Sub-Saharan Africa where Tanzania lies, small-scale farmers who lack resources for increasing crop productivity on nutrient-depleted soils may use additional forested lands to maintain production and their livelihoods [21].

Additionally, livestock keeping was among the land use practices being undertaken in the area. The observed livestock-keeping activities in the area were probably due to a lack of binding laws that restrict them from grazing in this corridor. WCST [22] stated that weak policy and law enforcement were the main conservation challenges facing wildlife corridors in Tanzania. This has been the factor leading to the immigration of pastoralists to this corridor from other areas. Elsewhere in Tanzania, Malmer and Nyberg, [23] Killebrew and Wolff, [24] attributed overgrazing to a lack of land management plan and weak laws.

Charcoal making and fuelwood extraction were identified as other major land use practices threatening the corridor. Charcoal was regarded as a profitable business in this area. Msuya et al. [25] stated that for Tanzania mainland, the demand for charcoal has constantly increased and prices were also rising. At the value of over TSHS 20 billion charcoal is considered as one of the highly valued industries which play a significant role in maintaining local communities' livelihoods' security in Tanzania [26]. Similarly, charcoal making and fuelwood collection are the main sources of energy for cooking since the Government had not yet provided a strategy for providing an alternative energy source [12]. Only about 14 percent of Tanzanians have access to electric power energy [27].

The results showed that various land use practices have far reaching implications on wildlife conservation in the corridor. These included loss of habitats and decreased animal species. The invasion caused by livestock, shifting agriculture, and charcoal burning were ranked as major factors degrading the corridor. Scientific studies have shown that animals are threatened by the presence of features like houses and farms located in their routes as substitutes of the natural vegetation cover [7, 4,12]. This scenario might have contributed to the local extinction of some mammal species in the area. These species included Black Rhino (*Diceros bicornis*), Cheetah (*Acinonyx jubatus*), Wildebeest (*Connochaetes taurinus*), Wild dogs (*Canis familiaris*), Impala (*Aepyceros melampus*), Blue duiker (*Cephalophus monticola*), and Eland (*Taurotragus oryx*). However, the population for some mammals had increased because of the beliefs attached to them such as Bush pig (*Potamochoerus porcus*) and Warthog (*Phacochoerus aethiopicus*) since the area is dominated by Muslims who do not feed on them. Other increased animals included Striped polecat (*Ictonyx striatus*), Hippopotamus (*Hippopotamus amphibious*), Crocodile (*Crocodilus niloticus*), Yellow baboon (*Papio cynocephalus*), and Monitor lizard (*Varanus indicus*).

Furthermore, there was a reduction of foraging ground for wild animals due to encroachment caused by agriculture and settlement. The area suitable for grazing by wildlife declined from 145 351 ha (82%) ha in 1975 to 86 168ha (43%) in 2011 (IRA, 2011). Human-wildlife contacts observed in the corridor had aggravated conflicts. Some of the reported conflicts included those related to crop damage, destruction of houses, livestock depredation, diseases (zoonotic) transmission, and illegal hunting, just to mention a few. However, the declining trend of wildlife population in this area could be a reflection of ecosystem degradation due to other factors than human-induced factors. Such factors could be a change in climatic condition which as well influences food availability.

Charcoal making and firewood collection require a large volume of wood which in turn depletes tree stocks resulting in various forms of environmental degradation such as soil erosion, lowering and affecting abundance and diversity of trees in an area of concern [28-30]. The demand for charcoal from the corridor was relatively increasing in which people were cutting both dead and green kinds of wood. The situation resulted in a bush clearing which caused patches of bare land hence negatively impacting the biodiversity. This was revealed on the changes seen in the classified satellite imageries from 1975 to 2011 (Figs 4, 5, and 6). The amount of charcoal that was carried out daily from the area was between 40 and 60 sacks. Furthermore, there are inadequate records of the extent to which illegal tree harvesting was carried out in the area but a habitat change in the traditional route must have acted as an impediment to the wild animal movement.

5. CONCLUSION AND RECOMMENDATION

The study has shown that although the Saadani-Wami-Mbiki Wildlife Corridor forms an important connection between the Saadani National Park and Wami-Mbiki WMA, its status has been decreasing with time as a result of various land use practices carried out in and around. There were nine recognized human-induced types of land use practices carried out in and around the corridor, among them being agriculture that was singled out as the major land use practice. This type of land use was mainly practiced along and within the corridor. Livestock keeping was the second activity but was mainly practiced by immigrants. Other activities included firewood collection, extraction of poles/withies, charcoal making, illegal hunting, fishing, sand extraction, mining, and logging which had profound negative impacts on the welfare and conservation status of the corridor. These land use practices were influenced by the increase in population and poverty of local communities along the Saadani-Wami-Mbiki Wildlife Corridor.

The vegetation cover of the corridor has been decreasing for over 36 years. This tendency has influenced the destruction of wildlife habitats, decrease in foraging ground, loss of natural vegetation, elimination of important cover for prey, interruption of animal movements, and blockage of the corridor. As a result, some mammal species have disappeared and others had their population decreased abundantly.

It is recommended that both Government and other conservation stakeholders should introduce and implement the community-based conservation approach so that the active involvement of the villagers in the protection of the wildlife in and outside this corridor is realized. This could be a solution to harmonise with the conservation of this corridor. Rural and poor
communities can engage in conservation activities if and only if co-operation and support are granted to them. Furthermore, it is recommended that The Government should support a land use management plan in villages bordering the wildlife corridors to reduce human pressure on natural resources found within. The Government should prepare village strategic land use plans, surveying villages, demarcate the corridors, and public natural resources available to have the proper use of the resources in the area.

CONSENT

As per international standard or university standard, respondents’ written consent has been collected and preserved by the author(s).

COMPETING INTERESTS

Authors have declared that no competing interests exist.

8. Residential status: a) Native……………..               b) Immigrant…………………….

9. If you are an immigrant, how long have you been in this area (years)…………………

10. What is your tribe?…………………………  From which Region?…………………………

B: Conservation Awareness

11. Do you know what wildlife corridor is:
   a) Yes…………………….                        b) No…………………….

12. What is the status/use of the corridor in the past

140
13. Do you think people are now practicing different land use systems in the corridor than in the past?
   a) Yes ............................................................. b) .............................................................

14. What is the current integrity status of the corridor?
   a) Excellent............................... b) Good..............................
   c) Fair............................... d) Bad..............................
   e) Worse..............................

15. Where do you cultivate the crops?
   a) Near the corridor...................... b) Far from the corridor......................

16. What are the activities that hamper/threat the integrity of the corridor? List them according to their importance in conservation activities.
   a) ........................................................................................................
   b) ........................................................................................................
   c) ........................................................................................................

17. What are the consequences of these activities to;
   a) Wild animals conservation................................................................
   b) Habitat............................................................................................

18. What is the current conservation status of the corridor
   ........................................................................................................

19. What are the current or the future plans conservation activities carried out in the corridor?
   ........................................................................................................

20. Are you aware about the consequences of human activities on the corridor?
   a) Yes........................................ b) No ........................................
   Elaborate............................................................................................

C: Human-Wildlife Interaction

21. Do you see wild animals in that area?
   a) ........................................ b) ........................................

22. If Yes, name them in major categories of wild animals that are seen in recent times, seen their signs, pellets, foot prints or heard of being exist here:
   a). Herbivores ........................................................................
   b). Predator ........................................................................
   c). Primates ........................................................................

23. What animals currently not seen but used to be seen and
   ........................................................................................................
   Why?...............................................................................................
24. In which season of the year normally has high population of wild animals in the area? 
   a) Dry season  
   b) Wet season  
   c) Both seasons  
   Reasons  

25. What is their direction during their movement?  
   a) From Saadani National Park to Wami-Mbiki Wildlife management Area  
   b) From Wami-Mbiki Wildlife management Area to Saadani National Park  
   c) From both direction  
   d) No idea  

26. Based on the list of animals above which are resident of the corridor and which are migratory?  
   a) Resident animals  
   b) Migratory animals  

27. What is your comment on the trend of animals?  
   a) Buffalo  
      a) Increasing  
      b) Decreasing  
      c) No idea  
   b) Zebra  
      a) Increasing  
      b) Decreasing  
      c) No idea  
   c) Wildebeest  
      a) Increasing  
      b) Decreasing  
      c) No idea  
   Reason  

D: Human activities  

28. What are the land use systems carried out along the corridor?  
   a) Cultivation  
   b) Livestock grazing  
   c) Charcoal burning  
   d) Hunting  
   e) Logging  
   f) Lumbering  
   g) Firewood  
   h) Others (specify)  

29. What is the intensity/state of these land use systems in the corridor?  
   a) Very high  
   b) High  
   c) Fair  
   d) Low  
   e) Very low  
   f) No idea  

30. Do these activities carried out legally?  
   a) Yes  
   b) No  
   c) No idea  

31. Why people prefer to take economic activities along the corridor rather than in other areas?  
   a)  
   b)  

32. What is the extent of people dependency to the corridor?  
   a) Very high  
   b) High  
   c) Fair  
   d) Low  
   e) Very low  
   f) No idea
33. What are the cultural activities carried out in the corridor?
   a) Ritual
   b) Medicinal
   c) Others (specify)

34. Is there any traditional method of conservation?
   a) Yes
   b) No

35. If yes, what is (are) the method(s)?
   a)
   b)

36. What is the effectiveness of these methods to the conservation activities?

E: Suggestions about Conservation

37. Do you think it is important to let the area (Wildlife corridor) to wildlife rather than human being?
   a) Yes
   b) No

38. Support your answer(s) above:

39. What do you think should be done in order that conservation of natural resources in the corridor becomes successful?

Appendix II: Checklist for Key Informants

1. What is the conservation status of the corridor?
2. Is there any policy or law or regulation that protects the corridor?
3. What are land use systems carried out along the corridor?
4. What is the extent of land use practices along the corridor?
5. How these activities do affect the conservation strategies of buffalo, zebra and wildebeest?
6. What are the consequences of those activities to the integrity of the corridor?
7. What are possible measures for remedy?
8. What are wild animals that are inside the corridor?
9. What were the common wild animals that were inside the corridor?
10. What are wild animals that are using the corridor as a migratory route?
11. What were the common wild animals that were using the corridor as a migratory route?
12. What conservation activities are currently undertaken?
13. What do you think should be done in order that conservation of natural resources in the corridor becomes successful?
